

NAME

hebctr – Translate to LaTeX the hash codes on a given line of a .hsh dictionary.

SYNOPSIS

```
cat ${HOME}/Utility/hebrew.hsh | ${HOME}/bin/exe/hebctr 99
```

DESCRIPTION

The program reads input lines until reaching the desired one, uses HSH2HB to expand the hash code on that line into LaTeX, and writes on standard out the transliteration of the word, the LaTeX to typeset it, and its English translation.

AUTHOR

Michael Kupferschmid

EXAMPLE

The command prototype above produced this output when I ran it

```
ahsher          \hebrew{resh}\segi{shin}\halfpatach{aleph}  that, which, who, where
```

At the time of this program execution line 99 of Utility/hebrew.hsh contained the hash code for the transliteration <ahsher>.
